Abstract

We present a method for verifying the correctness of imperative programs which is based on the automated transformation of their specifications. Given a program $\text{prog}$, we consider a partial correctness specification of the form $\{\varphi\} \text{prog} \{\psi\}$, where the assertions $\varphi$ and $\psi$ are predicates defined by a set $\text{Spec}$ of possibly recursive Horn clauses with linear arithmetic (LA) constraints in their premise (also called constrained Horn clauses). The verification method consists in constructing a set $\text{PC}$ of constrained Horn clauses whose satisfiability implies that $\{\varphi\} \text{prog} \{\psi\}$ is valid. We highlight some limitations of state-of-the-art constrained Horn clause solving methods, here called LA-solving methods, which prove the satisfiability of the clauses by looking for linear arithmetic interpretations of the predicates. In particular, we prove that there exist some specifications that cannot be proved valid by any of those LA-solving methods. These specifications require the proof of satisfiability of a set $\text{PC}$ of constrained Horn clauses that contain nonlinear clauses (that is, clauses with more than one atom in their premise). Then, we present a transformation, called linearization, that converts $\text{PC}$ into a set of linear clauses (that is, clauses with at most one atom in their premise). We show that several specifications that could not be proved valid by LA-solving methods, can be proved valid after linearization. We also present a strategy for performing linearization in an automatic way and we report on some experimental results obtained by using a preliminary implementation of our method.

This paper appears in Theory and Practice of Logic Programming (TPLP), Vol. 15 (4–5), Special issue on ICLP 2015.

KEYWORDS: Program verification, Partial correctness specifications, Horn clauses, Constraint Logic Programming, Program transformation.

1 Introduction

One of the most established methodologies for specifying and proving the correctness of imperative programs is based on the Floyd-Hoare axiomatic approach
(see (Hoare 1969), and also (Apt et al. 2009) for a recent presentation dealing with both sequential and concurrent programs). By following this approach, the partial correctness of a program prog is formalized by a triple \( \{ \phi \} prog \{ \psi \} \), also called partial correctness specification, where the precondition \( \phi \) and the postcondition \( \psi \) are assertions in first order logic, meaning that if the input values of prog satisfy \( \phi \) and program execution terminates, then the output values satisfy \( \psi \).

It is well-known that the problem of checking partial correctness of programs with respect to given preconditions and postconditions is undecidable. In particular, the undecidability of partial correctness is due to the fact that in order to prove in Hoare logic the validity of a triple \( \{ \phi \} prog \{ \psi \} \), one has to look for suitable auxiliary assertions, the so-called invariants, in an infinite space of formulas, and also to cope with the undecidability of logical consequence.

Thus, the best way of addressing the problem of the automatic verification of programs is to design incomplete methods, that is, methods based on restrictions of first order logic, which work well in the practical cases of interest. To achieve this goal, some methods proposed in the literature in recent years use linear arithmetic constraints as the assertion language and constrained Horn clauses as the formalism to express and reason about program correctness (Björner et al. 2012; De Angelis et al. 2014a; Grebenshchikov et al. 2012; Jaffar et al. 2012; Peralta et al. 1998; Podelski and Rybalchenko 2007; Rümmer et al. 2013).

Constrained Horn clauses are clauses with at most one atom in their conclusion and a conjunction of atoms and constraints over a given domain in their premise. In this paper we will only consider constrained Horn clauses with linear arithmetic constraints. The use of this formalism has the advantage that logical consequence for linear arithmetic constraints is decidable and, moreover, reasoning within constrained Horn clauses is supported by very effective automated tools, such as Satisfiability Modulo Theories (SMT) solvers (de Moura and Björner 2008; Cimatti et al. 2013; Rümmer et al. 2013) and constraint logic programming (CLP) inference systems (Jaffar and Maher 1994). However, current approaches to correctness proofs based on constrained Horn clauses have the disadvantage that they only consider specifications whose preconditions and postconditions are linear arithmetic constraints.

In this paper we overcome this limitation and propose an approach to proving general specifications of the form \( \{ \phi \} prog \{ \psi \} \), where \( \phi \) and \( \psi \) are predicates defined by a set of possibly recursive constrained Horn clauses (not simply linear arithmetic constraints), and \( prog \) is a program written in a C-like imperative language.

First, we indicate how to construct a set \( PC \) of constrained Horn clauses (\( PC \) stands for partial correctness), starting from: (i) the assertions \( \phi \) and \( \psi \), (ii) the program prog, and (iii) the definition of the operational semantics of the language in which \( prog \) is written, such that, if \( PC \) is satisfiable, then the partial correctness specification \( \{ \phi \} prog \{ \psi \} \) is valid.

Then, we formally show that there are sets \( PC \) of constrained Horn clauses encoding partial correctness specifications, whose satisfiability cannot be proved by current methods, here collectively called LA-solving methods (LA stands for linear
arithmetic). This limitation is due to the fact that LA-solving methods try to prove satisfiability by interpreting the predicates as linear arithmetic constraints.

For these problematic specifications, the set $PC$ of constrained Horn clauses contains non-linear clauses, that is, clauses with more than one atom in their premise.

Next, we present a transformation, which we call linearization, that converts the set $PC$ into a set of linear clauses, that is, clauses with at most one atom in their premise. We show that linearization preserves satisfiability and also increases the power of LA-solving, in the sense that several specifications that could not be proved valid by LA-solving methods, can be proved valid after linearization. Thus, linearization followed by LA-solving is strictly more powerful than LA-solving alone.

The paper is organized as follows. In Section 2 we show how a class of partial correctness specifications can be translated into constrained Horn clauses. In Section 3 we prove that LA-solving methods are inherently incomplete for proving the satisfiability of constrained Horn clauses. In Section 4 we present a strategy for automatically performing the linearization transformation, we prove that it preserves LA-solvability, and (in some cases) it is able to transform constrained Horn clauses that are not LA-solvable into constrained Horn clauses that are LA-solvable. Finally, in Section 5 we report on some preliminary experimental results obtained by using a proof-of-concept implementation of the method.

2 Translating Partial Correctness into Constrained Horn Clauses

We consider a C-like imperative programming language with integer variables, assignments, conditionals, while loops, and goto’s. An imperative program is a sequence of labeled commands (or commands, for short), and in each program there is a unique halt command that, when executed, causes program termination.

The semantics of our language is defined by a transition relation, denoted $\Rightarrow$, between configurations. Each configuration is a pair $\langle \ell: c, \delta \rangle$ of a labeled command $\ell: c$ and an environment $\delta$. An environment $\delta$ is a function that maps every integer variable identifier $x$ to its value $v$ in the integers $\mathbb{Z}$. The definition of the relation $\Rightarrow$ is similar to that of the ‘small step’ operational semantics presented in (Reynolds 1998), and is omitted. Given a program $prog$, we denote by $t_0: c_0$ its first labeled command.

We assume that all program executions are deterministic in the sense that, for every environment $\delta_0$, there exists a unique, maximal (possibly infinite) sequence of configurations, called computation sequence, of the form: $\langle t_0: c_0, \delta_0 \rangle \Rightarrow \langle t_1: c_1, \delta_1 \rangle \Rightarrow \cdots$. We also assume that every finite computation sequence ends in the configuration $\langle t_0: \text{halt}, \delta_n \rangle$, for some environment $\delta_n$. We say that a program $prog$ terminates for $\delta_0$ iff the computation sequence starting from the initial configuration $\langle t_0: c_0, \delta_0 \rangle$ is finite.
### 2.1 Specifying Program Correctness

First we need the following notions about constraints, constraint logic programming, and constrained Horn clauses. For related notions with which the reader is not familiar, he may refer to (Jaffar and Maher 1994; Lloyd 1987).

A **constraint** is a linear arithmetic equality (=) or inequality (>) over the integers \(Z\), or a conjunction or a disjunction of constraints. For example, \(2 \cdot X \geq 3 \cdot Y - 4\) is a constraint. We feel free to say ‘linear arithmetic constraint’, instead of ‘constraint’. We denote by \(\mathcal{C}_{LA}\) the set of all constraints. An **atom** is an atomic formula of the form \(p(t_1, \ldots, t_m)\), where \(p\) is a predicate symbol not in \{=, >\} and \(t_1, \ldots, t_m\) are terms. Let \(\text{Atom}\) be the set of all atoms. A **definite clause** is an implication of the form \(A \leftarrow c, G\), where in the conclusion (or head) \(A\) is an atom, and in the premise (or body) \(c\) is a constraint, and \(G\) is a (possibly empty) conjunction of atoms. A **constrained goal** (or simply, a **goal**) is an implication of the form \(\text{false} \leftarrow c, G\). A **constrained Horn clause** (CHC) (or simply, a **clause**) is either a definite clause or a constrained goal. A constraint logic program (or simply, a CLP program) is a set of definite clauses. A **clause over the integers** is a clause that has no function symbols except for integer constants, addition, and multiplication by integer constants.

The semantics of a constraint \(c\) is defined in terms of the usual interpretation, denoted by \(LA\), over the integers \(Z\). We write \(LA \models c\) to denote that \(c\) is true in \(LA\).

Given a set \(S\) of constrained Horn clauses, an **LA-interpretation** is an interpretation for the language of \(S\) that agrees with \(LA\) on the language of the constraints. An **LA-model** of \(S\) is an LA-interpretation that makes all clauses of \(S\) true. A set of constrained Horn clauses is **satisfiable** if it has an LA-model. A CLP program \(P\) is always satisfiable and has a **least LA-model**, denoted \(M(P)\). We have that a set \(S\) of constrained Horn clauses is **satisfiable** if \(S = P \cup G\), where \(P\) is a CLP program, \(G\) is a set of goals, and \(M(P) \models G\). Given a first order formula \(\varphi\), we denote by \(\exists(\varphi)\) its **existential closure** and by \(\forall(\varphi)\) its **universal closure**.

Throughout the paper we will consider partial correctness specifications which are particular triples of the form \{\(\varphi\)\} \(\text{prog}\) \{\(\psi\)\} defined as follows.

**Definition 1 (Functional Horn Specification)**

A partial correctness triple \{\(\varphi\)\} \(\text{prog}\) \{\(\psi\)\} is said to be a **functional Horn specification** if the following assumptions hold, where the predicates \(\text{pre}\) and \(f\) are assumed to be defined by a CLP program \(\text{Spec}\):

1. \(\varphi\) is the formula: \(z_1 = p_1 \wedge \ldots \wedge z_s = p_s \wedge \text{pre}(p_1, \ldots, p_k)\), where \(z_1, \ldots, z_s\) are the variables occurring in \(\text{prog}\), and \(p_1, \ldots, p_k\) are variables (distinct from the \(z_i\)’s), called **parameters** (informally, \(\text{pre}\) determines the initial values of the \(z_i\)’s);

2. \(\psi\) is the atom \(f(p_1, \ldots, p_s, z_k)\), where \(z_k\) is a variable in \(\{z_1, \ldots, z_s\}\) (informally, \(z_k\) is the variable whose final value is the result of the computation of \(f\));

3. \(f\) is a relation which is **total on \(\text{pre}\) and functional**, in the sense that the following two properties hold (informally, \(f\) is the function computed by \(\text{prog}\)):

   - (3.1) \(M(\text{Spec}) \models \forall p_1, \ldots, p_s. \text{pre}(p_1, \ldots, p_k) \rightarrow \exists y. f(p_1, \ldots, p_s, y)\)
   - (3.2) \(M(\text{Spec}) \models \forall p_1, \ldots, p_s, y_1, y_2. f(p_1, \ldots, p_s, y_1) \wedge f(p_1, \ldots, p_s, y_2) \rightarrow y_1 = y_2. \square\)

We say that a functional Horn specification \{\(\varphi\)\} \(\text{prog}\) \{\(\psi\)\} is **valid**, or \(\text{prog}\) is partially correct with respect to \(\varphi\) and \(\psi\), iff for all environments \(\delta_0\) and \(\delta_n\),
if \( M(\text{Spec}) \models \text{pre}(\delta_0(z_1),...,#\delta_0(z_k)) \) holds (in words, \( \delta_0 \) satisfies \( \text{pre} \)) and \( \{ \ell_0 : c_0, \delta_0 \} \) \( \Rightarrow^* \) \( \{ \ell_n : h, \delta_n \} \) holds (in words, \( \text{prog} \) terminates for \( \delta_0 \)) holds, then \( M(\text{Spec}) \models f(\delta_0(z_1),...,#\delta_0(z_k),\delta_n(z_k)) \) holds (in words, \( \delta_n \) satisfies the postcondition).

The relation \( r_{\text{prog}} \) computed by \( \text{prog} \) according to the operational semantics of the imperative language, is defined by the CLP program \( \text{OpSem} \) made out of: (i) the following clause \( R \) (where, as usual, variables are denoted by upper-case letters):

\( \text{R}. \ r_{\text{prog}}(P_1,...,P_s,Z_k) \leftarrow \text{initCf}(C_0,P_1,...,P_s), \text{reach}(C_0,C_h), \text{finalCf}(C_h,Z_k) \)

where:

(i.1) \( \text{initCf}(C_0,P_1,...,P_s) \) represents the initial configuration \( C_0 \), where the variables \( z_1,...,z_s \) are bound to the values \( P_1,...,P_s \), respectively, and \( \text{pre}(P_1,...,P_s) \) holds,

(ii) \( \text{reach}(C_0,C_h) \) represents the transitive closure \( \Rightarrow^* \) of the transition relation \( \Rightarrow \), which in turn is represented by a predicate \( \text{tr}(C_1,C_2) \) that encodes the operational semantics, that is, the interpreter of our imperative language, by relating a source configuration \( C_1 \) to a target configuration \( C_2 \),

(iii) \( \text{finalCf}(C_h,Z_k) \) represents the final configuration \( C_h \), where the variable \( z_k \) is bound to the value \( Z_k \),

and (ii) the clauses for the predicates \( \text{pre}(P_1,...,P_s) \) and \( \text{tr}(C_1,C_2) \). The clauses for the predicate \( \text{tr}(C_1,C_2) \) are defined as indicated in (De Angelis et al. 2014a), and are omitted for reasons of space.

\begin{example}[Fibonacci Numbers]
Let us consider the following program fibonacci, that returns as value of \( u \) the \( n \)-th Fibonacci number, for any \( n \geq 0 \), having initialized \( u \) to 1 and \( v \) to 0.

\[ \begin{array}{l}
0: \text{while} \ (\text{n}>0) \ {\{ t=u; \ u=u+v; \ v=t; \ n=n-1 \}} \ \text{fibonacci} \\
\text{h:} \ \text{halt}
\end{array} \]

The following is a functional Horn specification of the partial correctness of the program fibonacci:

\( \{ \text{n=N}, \text{N}>0, \text{u=1}, \text{v=0}, \text{t=0} \} \ \text{fibonacci} \ \{ \text{fib(N,u)} \} \)

where \( N \) is a parameter and \( \text{fib} \) is defined by the following CLP program:

\( \begin{array}{l}
\text{S1. fib(0,1).} \\
\text{S2. fib(1,1).} \\
\text{S3. fib(N3,F3):=} \text{N1>0}, \text{N2=N1+1}, \text{N3=N2+1}, \text{F3=F1+F2}, \text{fib(N1,F1)}, \text{fib(N2,F2)}
\end{array} \)

For reasons of conciseness, in the above specification (i) we have slightly deviated from Definition 1. In particular, we did not introduce the predicate symbol \( \text{pre} \), and in the precondition and postcondition we did not introduce the parameters which have constant values.

The relation \( r_{\text{fibonacci}} \) computed by the program fibonacci according to the operational semantics, is defined by the following CLP program:

\( \begin{array}{l}
\text{R1. r_fibonacci(N,U) :- initCf(C0,N), reach(C0,Ch), finalCf(Ch,U).} \\
\text{R2. initCf(cf(LC,E),N) :- N>0, U=1, V=0, T=0, firstCmd(LC),} \\
\text{env((n,N),E), env((u,U),E), env((v,V),E), env((t,T),E).} \\
\text{R3. finalCf(cf(LC,E),U) :- haltCmd(LC), env((u,U),E).}
\end{array} \)

where: (i) \( \text{firstCmd(LC)} \) holds for the command with label 0 of the program fibonacci; (ii) \( \text{env((x,X),E)} \) holds iff in the environment \( E \) the variable \( x \) is bound to the
value of $X$; (iii) in the initial configuration $C_0$ the environment $E$ binds the variables $n, u, v, t$ to the values $\mathbb{N} (>0), 1, 0, 0$, respectively; and (iv) $haltCmd(LC)$ holds for the labeled command $h: halt$.

2.2 Encoding Specifications into Constrained Horn Clauses

In this section we present the encoding of the validity problem of functional Horn specifications into the satisfiability problem of CHC’s.

For reasons of simplicity we assume that in $Spec$ no predicate depends on $f$ (possibly, except for $f$ itself), that is, $Spec$ can be partitioned into two sets of clauses, call them $F_{def}$ and $Aux$, where $F_{def}$ is the set of clauses with head predicate $f$, and $f$ does not occur in $Aux$.

**Theorem 1 (Partial Correctness)**

Let $F_{pcorr}$ be the set of goals derived from $F_{def}$ as follows: for each clause $D \in F_{def}$ of the form $f(X_1, \ldots, X_s, Y) \leftarrow B$, (1) every occurrence of $f$ in $D$ (and, in particular, in $B$) is replaced by $r_{prog}$, thereby deriving a clause $E$ of the form: $r_{prog}(X_1, \ldots, X_s, Y) \leftarrow \tilde{B}$, (2) clause $E$ is replaced by the goal $G$: $false \leftarrow Y \neq Z$, $r_{prog}(X_1, \ldots, X_s, Z) = \tilde{B}$, where $Z$ is a new variable, and (3) goal $G$ is replaced by the following two goals:

- $G_1$. $false \leftarrow Y > Z$, $r_{prog}(X_1, \ldots, X_s, Z) = \tilde{B}$
- $G_2$. $false \leftarrow Y < Z$, $r_{prog}(X_1, \ldots, X_s, Z) = \tilde{B}$

Let $PC$ be the set $F_{pcorr} \cup Aux \cup OpSem$ of CHC’s. We have that: if $PC$ is satisfiable, then $\{\varphi\}_{prog} \{\psi\}$ is valid.

The proof of this theorem and of the other facts presented in this paper can be found in the appendix. In our Fibonacci example (see Example 1) the set $F_{def}$ of clauses is the entire set $Spec_{fibonacci}$ and $Aux = \emptyset$. According to Points (1)-(3) of Theorem 1, from $Spec_{fibonacci}$ we derive the following six goals:

- $G_1$. $false :- F > 1, r_{fibonacci}(0,F)$.  
- $G_2$. $false :- F < 1, r_{fibonacci}(0,F)$.  
- $G_3$. $false :- F > 1, r_{fibonacci}(1,F)$.  
- $G_4$. $false :- F < 1, r_{fibonacci}(1,F)$.  
- $G_5$. $false :- N1 > 0, N2 = N1 + 1, N3 = N2 + 1, F3 > F1 + F2, r_{fibonacci}(N1,F1), r_{fibonacci}(N2,F2), r_{fibonacci}(N3,F3)$.  
- $G_6$. $false :- N1 > 0, N2 = N1 + 1, N3 = N2 + 1, F3 < F1 + F2, r_{fibonacci}(N1,F1), r_{fibonacci}(N2,F2), r_{fibonacci}(N3,F3)$.

Thus, in order to prove the validity of the specification (‡) above, since $Aux = \emptyset$, it is enough to show that the set $PC_{fibonacci} = \{G_1, \ldots, G_6\} \cup OpSem_{fibonacci}$ of CHC’s is satisfiable.

3 A Limitation of $LA$-solving Methods

Now we show that there are sets of CHC’s that encode partial correctness specifications whose satisfiability cannot be proved by $LA$-solving methods.

A **symbolic interpretation** is a function $\Sigma : Atom \to C_{LA}$ such that, for every $A \in Atom$ and substitution $\vartheta$, $\Sigma(A\vartheta) = \Sigma(A)\vartheta$. Given a set $S$ of CHC’s, a symbolic
interpretation $\Sigma$ is an LA-solution of $S$ iff, for every clause $A_0 \leftarrow c, A_1, \ldots, A_n$ in $S$, we have that $LA \models (c \land \Sigma(A_1) \land \ldots \land \Sigma(A_n)) \rightarrow \Sigma(A_0)$.

We say that a set $S$ of CHC’s is LA-solvable if there exists an LA-solution of $S$. Clearly, if a set of CHC’s is LA-solvable, then it is satisfiable. The converse does not hold as we now show.

**Theorem 2**

There are sets of constrained Horn clauses which are satisfiable and not LA-solvable.

*Proof.* Let $PC_{\text{fibonacci}}$ be the set of clauses that encode the validity of the Fibonacci specification (1). $PC_{\text{fibonacci}}$ is satisfiable, because $r_{\text{fibonacci}}(N,F)$ holds iff $F$ is the $N$-th Fibonacci number, and hence the bodies of $G_1, \ldots, G_6$ are false. (This fact will also be proved by the automatic method presented in Section 4.)

Now we prove, by contradiction, that $PC_{\text{fibonacci}}$ is not LA-solvable. Suppose that there exists an LA-solution $\Sigma$ of $PC_{\text{fibonacci}}$. Let $\Sigma(r_{\text{fibonacci}}(N,F))$ be a constraint $c(N,F)$. To keep our proof simple, we assume that $c(N,F)$ is defined by a conjunction of linear arithmetic inequalities (that is, $c(N,F)$ is a convex constraint), but our argument can easily be generalized to any constraint in $C_{LA}$. By the definition of LA-solution, we have that:

(P1) $LA \not\models \exists(N1 \geq 0, N2 = N1 + 1, N3 = N2 + 1, F3 > F1 + F2, c(N1, F1), c(N2, F2), c(N3, F3))$

(P2) $M(OpSem_{\text{fibonacci}}) \models \forall (r_{\text{fibonacci}}(N,F) \rightarrow c(N,F))$

Property (P1) follows from the fact that, in particular, an LA-solution satisfies goal $G_5$. Property (P2) follows from the fact that an LA-solution satisfies all clauses of $OpSem_{\text{fibonacci}}$ and $M(OpSem_{\text{fibonacci}})$ defines the least $r_{\text{fibonacci}}$ relation that satisfies those clauses.

From Property (P2) and from the fact that $r_{\text{fibonacci}}(N,F)$ holds iff $F$ is the $N$-th Fibonacci number (and hence $F$ is an exponential function of $N$), it follows that $c(N,F)$ is a conjunction of the form $c_1(N,F), \ldots, c_k(N,F)$, where, for $i = 1, \ldots, k$, with $k \geq 0$, $c_i(N,F)$ is either (A) $N > a_i$, for some integer $a_i$, or (B) $F > a_i \cdot N + b_i$, for some integers $a_i$ and $b_i$. (No constraints of the form $F < a_i \cdot N + b_i$ are possible, as shown in Figure 1.)

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fibonacci_diagram.png}
\caption{The relation $r_{\text{fibonacci}}(N,F)$ and the convex constraint $c(N,F)$.}
\end{figure}

By replacing $c(N1, F1), c(N2, F2)$, and $c(N3, F3)$ by the corresponding conjunctions of atomic constraints of the forms (A) and (B), and eliminating the occurrences of $F1, F2, N2$, and $N3$, from (P1) we get:

(P3) $LA \not\models \exists(N1 \geq 0, F3 > p_1, \ldots, F3 > p_k)$

7
where, for $i = 1, \ldots, n$, $p_i$ is a linear polynomial in the variable $N_1$. Then, the constraint $N_1 \geq 0, F_3 > p_1, \ldots, F_3 > p_n$ is satisfiable and Property ($P3$) is false. Thus, the assumption that $PC_{fibonacci}$ is LA-solvable is false, and we get the thesis. □

4 Increasing the Power of LA-solving Methods by Linearization

A weakness of the LA-solving methods is that they look for LA-solutions constructed from single atoms, and by doing so they may fail to discover that a goal is satisfiable because a conjunction of atoms in its premise is unsatisfiable, in spite of the fact that each of its conjoint atoms is satisfiable. For instance, in our Fibonacci example the premise of goal $G5$ contains three atoms with predicate $r_{fibonacci}$ and our proof of Section 3 shows that, even if the premise of $G5$ is unsatisfiable, there is no constraint which is an LA-solution of the clauses defining $r_{fibonacci}$ that, when substituted for each $r_{fibonacci}$ atom, makes that premise false. Thus, the notion of LA-solution shows some weakness when dealing with nonlinear clauses, that is, clauses whose premise contains more than one atom (besides constraints).

In this section we present an automatic transformation of constrained Horn clauses that has the objective of increasing the power of LA-solving methods. The core of the transformation, called linearization, takes a set of possibly nonlinear constrained Horn clauses and transforms it into a set of linear clauses, that is, clauses whose premise contains at most one atom (besides constraints). After performing linearization, the LA-solving methods are able to exploit the interactions among several atoms, instead of dealing with each atom individually. In particular, an LA-solution of the linearized set of clauses will map a conjunction of atoms to a constraint. We will show that linearization preserves the existence of LA-solutions and, in some cases (including our Fibonacci example), transforms a set of clauses which is not LA-solvable into a set of clauses that is LA-solvable.

Our transformation technique is made out of the following two steps: (1) RI: Removal of the interpreter, and (2) LIN: Linearization. These steps are performed by using the transformation rules for CLP programs presented in (Etalle and Gabbrielli 1996), that is: unfolding (which consists in applying a resolution step and a constraint satisfiability test), definition (which introduces a new predicate defined in terms of old predicates), and folding (which redefines old predicates in terms of new predicates introduced by the definition rule).

4.1 RI: Removal of the Interpreter

This step is a variant of the removal of the interpreter transformation presented in (De Angelis et al. 2014a). In this step a specialized definition for $r_{prog}$ is derived by transforming the CLP program $OpSem$, thereby getting a new CLP program $OpSem_{RI}$ where there are no occurrences of the predicates $initCf$, $finalCf$, $reach$, and $tr$, which as already mentioned encodes the interpreter of the imperative language in which $prog$ is written. (See appendix for more details.)

By a simple extension of the results presented in (De Angelis et al. 2014a), it can be shown that the RI transformation always terminates, preserves satisfiability,
and transforms $\text{OpSem}$ into a set of linear clauses over the integers. It can also be shown that the removal of the interpreter preserves LA-solvability. Thus, we have the following result.

**Theorem 3**

Let $\text{OpSem}$ be a CLP program constructed starting from any given imperative program $\text{prog}$. Then the RI transformation terminates and derives a CLP program $\text{OpSem}_{RI}$ such that:

1. $\text{OpSem}_{RI}$ is a set of linear clauses over the integers;
2. $\text{OpSem} \cup \text{Aux} \cup F_{\text{pcorr}}$ is satisfiable if $\text{OpSem}_{RI} \cup \text{Aux} \cup F_{\text{pcorr}}$ is satisfiable;
3. $\text{OpSem} \cup \text{Aux} \cup F_{\text{pcorr}}$ is LA-solvable if $\text{OpSem}_{RI} \cup \text{Aux} \cup F_{\text{pcorr}}$ is LA-solvable.

In the Fibonacci example, the input of the RI transformation is $\text{OpSem}_{\text{Fibonacci}}$. The output of the RI transformation consists of the following three clauses:

1. $\text{r}_{\text{fibonacci}}(N,F) : \iff N >= 0, U=1, V=0, T=0, \text{r}(N,U,V,T,N1,F,V1,T1)$.
2. $\text{r}(N,U,V,T,N,U,V,T) : \iff N < 0$.
3. $\text{r}(N,U,V,T,N2,U2,V2,T2) : \iff N >= 1, N1 = N-1, U1 = U+V, V1 = U, T1 = U, \text{r}(N1,U1,V1,T1,N2,U2,V2,T2)$.

where $\text{r}$ is a new predicate symbol introduced by the RI transformation.

As stated by Theorem 3, $\text{OpSem}_{RI}$ is a set of clauses over the integers. Since the clauses of the specification $\text{Spec}$ define computable functions from $\mathbb{Z}^n$ to $\mathbb{Z}$, without loss of generality we may assume that also the clauses in $\text{Aux} \cup F_{\text{pcorr}}$ are over the integers (Sebelik and Stepánek 1982). From now on we will only deal with clauses over the integers, and we will feel free to omit the qualification ‘over the integers’.

### 4.2 LIN: Linearization

The linearization transformation takes as input the set $\text{OpSem}_{RI} \cup \text{Aux} \cup F_{\text{pcorr}}$ of constrained Horn clauses and derives a new, equisatisfiable set $\text{TransfCls}$ of linear constrained Horn clauses.

In order to perform linearization, we assume that $\text{Aux}$ is a set of linear clauses. This assumption, which is not restrictive because any computable function on the integers can be encoded by linear clauses (Sebelik and Stepánek 1982), simplifies the proof of termination of the transformation.

The linearization transformation is described in Figure 2. Its input is constructed by partitioning $\text{OpSem}_{RI} \cup \text{Aux} \cup F_{\text{pcorr}}$ into a set $\text{LCls}$ of linear clauses and a set $\text{NLGls}$ of nonlinear goals. $\text{LCls}$ consists of $\text{Aux}$, $\text{OpSem}_{RI}$ (which, by Theorem 3, is a set of linear clauses), and the subset of linear goals in $F_{\text{pcorr}}$. $\text{NLGls}$ consists of the set of nonlinear goals in $F_{\text{pcorr}}$.

When applying linearization we use the following transformation rule.

**Unfolding Rule.** Let $\text{Cls}$ be a set of constrained Horn clauses. Given a clause $C$ of the form $H \leftarrow c, Ls, A, Rs$ let us consider the set $\{K_i \leftarrow c_i, B_i \mid i = 1, \ldots, m\}$ made out of the (renamed apart) clauses of $\text{Cls}$ such that, for $i = 1, \ldots, m$, $A$ is unifiable with $K_i$ via the most general unifier $\vartheta_i$ and $(c, c_i) \vartheta_i$ is satisfiable. By unfolding $C$ with respect to $A$ using $\text{Cls}$, we derive the set $\{(H \leftarrow c, c_i, Ls, B_i, Rs) \vartheta_i \mid i = 1, \ldots, m\}$ of clauses.

9
Input: (i) A set $\text{LCls}$ of linear clauses, and (ii) a set $\text{Gls}$ of nonlinear goals.
Output: A set $\text{TransfCls}$ of linear clauses.

Initialization: $\text{NLCls} := \text{Gls}; \text{Defs} := \emptyset; \text{TransfCls} := \text{LCls};$

while there is a clause $C$ in $\text{NLCls}$ do

Unfolding: From clause $C$ derived a set $U(C)$ of clauses by unfolding $C$ with respect to every atom occurring in its body using $\text{LCls}$;

Rewrite each clause in $U(C)$ to a clause of the form $H ← c, A_1, \ldots, A_k$, such that, for $i = 1, \ldots, k$, $A_i$ is of the form $p(X_1, \ldots, X_m)$;

Definition & Folding:

$F(C) := U(C);$ for every clause $E ∈ F(C)$ of the form $H ← c, A_1, \ldots, A_k$ do

if in $\text{Defs}$ there is no clause of the form $\text{newp}(X_1, \ldots, X_t) ← A_1, \ldots, A_k$, where $\{X_1, \ldots, X_t\} = \text{vars}(A_1, \ldots, A_k) ∩ \text{vars}(H, c)$

then add $\text{newp}(X_1, \ldots, X_t) ← A_1, \ldots, A_k$ to $\text{Defs}$ and to $\text{NLCls}$;

$F(C) := (F(C) − \{E\}) ∪ \{H ← c, \text{newp}(X_1, \ldots, X_t)\}$
end-for

$\text{NLCls} := \text{NLCls} − \{C\}; \text{TransfCls} := \text{TransfCls} ∪ F(C);$ end-while

Figure 2. LIN: The linearization transformation.

It is easy to see that, since $\text{LCls}$ is a set of linear clauses, only a finite number of new predicates can be introduced by any sequence of applications of Definition & Folding, and hence the linearization transformation terminates. Moreover, the use of the unfolding, definition, and folding rules according to the conditions indicated in (Etalle and Gabbrielli 1996), guarantees the equivalence with respect to the least LA-model, and hence the equisatisfiability of $\text{LCls} ∪ \text{Gls}$ and $\text{TransfCls}$. Thus, we have the following result.

Theorem 4 (Termination and Correctness of Linearization)

Let $\text{LCls}$ be a set of linear clauses and $\text{Gls}$ be a set of nonlinear goals. The linearization transformation terminates for the input set of clauses $\text{LCls} ∪ \text{Gls}$, and the output $\text{TransfCls}$ is a set of linear clauses. Moreover, $\text{LCls} ∪ \text{Gls}$ is satisfiable iff $\text{TransfCls}$ is satisfiable.

Let us consider again the Fibonacci example. We apply the linearization transformation to the set $\{E_1, E_2, E_3\}$ of linear clauses, and to the nonlinear goal $G_5$. For brevity, we omit to consider the cases where the goals $G_1, \ldots, G_4, G_6$ are taken as input to the linearization transformation.

After Initialization we have that $\text{NLCls} = \{G_5\}, \text{Defs} = \emptyset$, and $\text{TransfCls} = \{E_1, E_2, E_3\}$. By applying the Unfolding step to $G_5$ we derive:

$C_1. \text{false} :- N_1=0, N_2=N_1+1, N_3=N_2+1, F_3=F_1+F_2, U=1, V=0,$

$\text{r}(N_1, U, V, V, X_1, F_1, Y_1, Z_1), \text{r}(N_2, U, V, X_2, F_2, Y_2, Z_2), \text{r}(N_3, U, V, X_3, F_3, Y_3, Z_3).$

Next, by Definition & Folding, the following clause is added to $\text{NLCls}$ and $\text{Defs}$:

$C_2. \text{new1}(N_1, U, V, F_1, N_2, F_2, N_3, F_3) :- \text{r}(N_1, U, V, X_1, F_1, Y_1, Z_1),$ 

$\text{r}(N_2, U, V, X_2, F_2, Y_2, Z_2), \text{r}(N_3, U, V, X_3, F_3, Y_3, Z_3).$

and clause $C_1$ is folded using $C_2$, thereby deriving the following linear clause:

$C_3. \text{false} :- N_1=0, N_2=N_1+1, N_3=N_2+1, F_3=F_1+F_2, U=1, V=0,$

$\text{new1}(N_3, U, V, F_3, N_2, F_2, N_1, F_1).$

At the end of the first execution of the body of the while-do loop we have: $\text{NLCls} =$

\[
\begin{align*}
&\text{false} :- N_1=0, N_2=N_1+1, N_3=N_2+1, F_3=F_1+F_2, U=1, V=0,
&\text{new1}(N_3, U, V, F_3, N_2, F_2, N_1, F_1),
&\text{new1}(N_1, U, V, X_1, F_1, Y_1, Z_1),
&\text{r}(N_1, U, V, V, X_1, F_1, Y_1, Z_1),
&\text{r}(N_2, U, V, V, X_2, F_2, Y_2, Z_2),
&\text{r}(N_3, U, V, V, X_3, F_3, Y_3, Z_3).\end{align*}
\]
Now, the linearization transformation continues by processing clause \(C2\). During its execution, linearization introduces two new predicates defined by the following two clauses:

\[
\]
\[
\text{C5. new3}(N2, U, V, F2, N1, F1) :- r(N1, U, V, V, X1, F1, Y1, Z1), r(N2, U, V, X2, F2, Y2, Z2).
\]

The transformation terminates when all clauses derived by unfolding can be folded using clauses in \(\text{Defs}\), without introducing new predicates. The output of the transformation is a set of linear clauses (listed in the appendix) which is \(\text{LA-solvable}\), as reported on line 4 of Table 1 in the next section.

In general, there is no guarantee that we can automatically transform any given satisfiable set of clauses into an \(\text{LA-solvable}\) one. In fact, such a transformation cannot be algorithmic because, for constrained Horn clauses, the problem of satisfiability is not semidecidable, while the problem of \(\text{LA-solvability}\) is semidecidable (indeed, the set of symbolic interpretations is recursively enumerable and the problem of checking whether or not a symbolic interpretation is an \(\text{LA}\)-solution is decidable). However, the linearization transformation cannot decrease \(\text{LA-solvability}\), as the following theorem shows.

**Theorem 5 (Monotonicity with respect to \(\text{LA}\)-solvability)**

Let \(\text{TransfCls}\) be obtained by applying the linearization transformation to \(\text{LCl}\) \(\cup\) \(\text{Gls}\). If \(\text{LCl}\) \(\cup\) \(\text{Gls}\) is \(\text{LA-solvable}\), then \(\text{TransfCls}\) is \(\text{LA-solvable}\).

Since there are cases where \(\text{LCl}\) \(\cup\) \(\text{Gls}\) is not \(\text{LA-solvable}\), while \(\text{TransfCls}\) is \(\text{LA-solvable}\) (see the Fibonacci example above and some more examples in the following section), as a consequence of Theorem 5 we get that the combination of \(\text{LA}\)-solving and linearization is strictly more powerful than \(\text{LA}\)-solving alone.

## 5 Experimental Results

We have implemented our verification method by using the VeriMAP system (De Angelis et al. 2014b). The implemented tool consists of four modules, which we have depicted in Figure 3. The first module, given the imperative program \(\text{prog}\) and its specification \(\text{Spec}\), generates the set \(\text{PC}\) of constrained Horn clauses (see Theorem 1). \(\text{PC}\) is then given as input to the module RI that removes the interpreter. Then, the module LIN performs the linearization transformation. Finally, the resulting linear clauses are passed to the \(\text{LA}\)-solver, consisting of VeriMAP together with an SMT solver, which is either Z3 (de Moura and Bjørner 2008) or MathSAT (Cimatti et al. 2013) or Eldarica (Rümmer et al. 2013).

![Figure 3. Our software model checker that uses the linearization module LIN.](image-url)
strength reduction, a real-world optimization technique\(^1\). In Table 1 we report the results of our experiments\(^2\).

One can see that linearization takes very little time compared to the total verification time. Moreover, linearization is necessary for the verification of 14 out of 19 programs (including fibonacci), which otherwise cannot be proved correct with respect to their specifications. In the two columns under LA-solving-1 we report the results obtained by giving as input to the Z3 and Eldarica solvers the set PC generated by the RI module. Under LA-solving-1 we do not have a column for MathSAT, because the version of this solver used in our experiments (namely, MSATC3) cannot deal with nonlinear CHC’s, and therefore it cannot be applied before linearization. In the last three columns of Table 1 we report the results obtained by giving as input to VeriMAP (and the solvers Z3, MathSAT, and Eldarica, respectively) the clauses obtained after linearization.

Unsurprisingly, for the verification problems where linearization is not necessary, our technique may deteriorate the performance, although in most of these problems the solving time does not increase much.

Table 1. Columns RI and LIN show the times (in seconds) taken for removal of the interpreter and linearization. The two columns under LA-solving-1 show the times taken by Z3 and Eldarica for solving the problems after RI alone. The three columns under LA-solving-2 show the times taken by VeriMAP together with Z3, MathSAT, and Eldarica, after RI and LIN. The timeout TO occurs after 120 seconds.

6 Conclusions and Related Work

We have presented a method for proving partial correctness specifications of programs, given as Hoare triples of the form \{φ\} prog \{ψ\}, where the assertions φ and ψ are predicates defined by a set of possibly recursive, definite CLP clauses. Our verification method is based on:

- **Step (1)** a translation of a given specification into a set of constrained Horn clauses (that is, a CLP program together with one or more goals),
- **Step (2)** an unfold/fold transformation strategy, called linearization, which derives linear clauses (that is, clauses with at most one atom in their body), and
- **Step (3)** an LA-solver that attempts to prove the satisfiability of constrained Horn clauses by interpreting predicates as linear arithmetic constraints.

We have formally proved that the method which uses linearization is strictly more powerful than the method that applies Step (3) immediately after Step (1). We have also developed a proof-of-concept implementation of our method by using the VeriMAP verification system (De Angelis et al. 2014b) together with various state-of-the-art solvers (namely, Z3 (de Moura and Bjørner 2008), MathSAT (Cimatti et al. 2013), and Eldarica (Rümmer et al. 2013)), and we have shown that our method works on several verification problems. Although these problems refer to quite simple specifications, some of them cannot be solved by using the above mentioned solvers alone.

The use of transformation-based methods in the field of program verification has recently gained popularity (see, for instance, (Albert et al. 2007; De Angelis et al. 2014a; Fioravanti et al. 2013; Kańe and Gallagher 2015; Leuschel and Massart 2000; Lisitsa and Nemytykh 2008; Peralta et al. 1998)). However, fully automated methods based on various notions of partial deduction and CLP program specialization cannot achieve the same effect as linearization. Indeed, linearization requires the introduction of new predicates corresponding to conjunctions of old predicates, whereas partial deduction and program specialization can only introduce new predicates that correspond to instances of old predicates. In order to derive linear clauses, one could apply conjunctive partial deduction (De Schreye et al. 1999), which essentially is equivalent to unfold/fold transformation. However, to the best of our knowledge, this application of conjunctive partial deduction to the field of program verification has not been investigated so far.

The use of linear arithmetic constraints for program verification has been first proposed in the field of abstract interpretation (Cousot and Cousot 1977), where these constraints are used for approximating the set of states that are reachable during program execution (Cousot and Halbwachs 1978). In the field of logic programming, abstract interpretation methods work similarly to LA-solving for constrained Horn clauses, because they both look for interpretations of predicates as linear arithmetic constraints that satisfy the program clauses (see, for instance, (Benoy and King 1997)). Thus, abstract interpretation methods suffer from the same theoretical limitations we have pointed out in this paper for LA-solving methods.

One approach that has been followed for overcoming the limitations related to the use of linear arithmetic constraints is to devise methods for generating polynomial invariants and proving specifications with polynomial arithmetic con-
straints (Rodríguez-Carbonell and Kapur 2007a; Rodríguez-Carbonell and Kapur 2007b). This approach also requires the development of solvers for polynomial constraints, which is a very complex task on its own, as in general the satisfiability of these constraints on the integers is undecidable (Matijasevic 1970). In contrast, the approach presented in this paper has the objective of transforming problems which would require the proof of nonlinear arithmetic assertions into problems which can be solved by using linear arithmetic constraints. We have shown some examples (such as the fibonacci program) where we are able to prove specifications whose post-condition is an exponential function.

An interesting issue for future research is to identify general criteria to answer the following question: Given a class $D$ of constraints and a class $H$ of constrained Horn clauses, does the satisfiability of a finite set of clauses in $H$ imply its $D$-solvability? Theorem 2 provides a negative answer to this question when $D$ is the class of LA constraints and $H$ is the class of all constrained Horn clauses.

Appendix

For the proof of Theorem 1 we need the following lemma.

Lemma 1. (i) The relation $r_{prog}$ defined by $OpSem$ is a functional relation, that is, $M(\mathit{OpSem}) = \forall p_1, \ldots, p_s, y_1, y_2. r_{prog}(p_1, \ldots, p_s, y_1) \land r_{prog}(p_1, \ldots, p_s, y_2) \rightarrow y_1 = y_2$.

(ii) A program $\mathit{prog}$ terminates for an environment $\delta_0$ such that $\delta_0(z_1) = p_1, \ldots, \delta_0(z_s) = p_s$ and $\mathit{pre}(p_1, \ldots, p_s)$ holds, iff

$M(\mathit{OpSem}) = \mathit{pre}(p_1, \ldots, p_s) \rightarrow \exists y. r_{prog}(p_1, \ldots, p_s, y)$.

Proof. Since the program $\mathit{prog}$ is deterministic, the predicate $r_{prog}$ defined by $OpSem$ is a functional relation (which might not be total on $\mathit{pre}$, as $\mathit{prog}$ might not terminate). Moreover, a program $\mathit{prog}$, with variables $z_1, \ldots, z_s$, terminates for an environment $\delta_0$ such that: (i) $\delta_0(z_1) = p_1, \ldots, \delta_0(z_s) = p_s$, and (ii) $\delta_0$ satisfies $\mathit{pre}$, iff $\exists y. r_{prog}(p_1, \ldots, p_s, y)$ holds in $M(\mathit{OpSem})$.$\blacksquare$

Proof of Theorem 1 (Partial Correctness).

Let $\mathit{dom}_r(X_1, \ldots, X_s)$ be a predicate that represents the domain of the functional relation $r_{prog}$. We assume that $\mathit{dom}_r(X_1, \ldots, X_s)$ is defined by a set $\mathit{Dom}$ of clauses, using predicate symbols not in $\mathit{OpSem} \cup \mathit{Spec}$, such that

$M(\mathit{OpSem} \cup \mathit{Dom}) \models \forall X_1, \ldots, X_s. (\exists Y. r_{prog}(X_1, \ldots, X_s, Y) \leftrightarrow \mathit{dom}_r(X_1, \ldots, X_s))$ \hspace{1cm} (1)

Let us denote by $\mathit{Spec}^\sharp$ the set of clauses obtained from $\mathit{Spec}$ by replacing each clause $f(X_1, \ldots, X_s, Y) \leftarrow B$ by the clause $f(X_1, \ldots, X_s, Y) \leftarrow \mathit{dom}_r(X_1, \ldots, X_s), B$. Then, for all integers $p_1, \ldots, p_s, y$,

$M(\mathit{Spec}^\sharp \cup \mathit{Dom}) \models f(p_1, \ldots, p_s, y)$ implies $M(\mathit{Spec}) \models f(p_1, \ldots, p_s, y)$ \hspace{1cm} (2)

Moreover, let us denote by $\mathit{Spec}'$ the set of clauses obtained from $\mathit{Spec}^\sharp$ by replacing all occurrences of $f$ by $r_{prog}$. We show that $M(\mathit{OpSem} \cup \mathit{Aux} \cup \mathit{Dom}) \models \mathit{Spec}'$.

Let $S$ be any clause in $\mathit{Spec}'$. If $S$ belongs to $\mathit{Aux}$, then $M(\mathit{OpSem} \cup \mathit{Aux}) \models S$. Otherwise, $S$ is of the form $r_{prog}(X_1, \ldots, X_s, Y) \leftrightarrow \mathit{dom}_r(X_1, \ldots, X_s), \tilde{B}$ and, by construction, in $F_{\mathit{corr}}$ there are two goals

$G_1$: false $\leftarrow Y > Z, r_{prog}(X_1, \ldots, X_s, Z), \tilde{B}$, and

$G_2$: false $\leftarrow Y < Z, r_{prog}(X_1, \ldots, X_s, Z), \tilde{B}$

such that $\mathit{OpSem} \cup \mathit{Aux} \cup \{G_1, G_2\}$ is satisfiable. Then,

$M(\mathit{OpSem} \cup \mathit{Aux}) \models \neg \exists Y \neq Z \land r_{prog}(X_1, \ldots, X_s, Z) \land \tilde{B}$

Since $M(\mathit{OpSem} \cup \mathit{Dom}) \models r_{prog}(X_1, \ldots, X_s, Z) \rightarrow \mathit{dom}_r(P_1, \ldots, P_s)$, we also have that

$M(\mathit{OpSem} \cup \mathit{Aux} \cup \mathit{Dom}) \models \neg \exists Y \neq Z \land \mathit{dom}_r(X_1, \ldots, X_s) \land r_{prog}(X_1, \ldots, X_s, Z) \land \tilde{B}$

From the functionality of $r_{prog}$ it follows that

$M(\mathit{OpSem} \cup \mathit{Aux} \cup \mathit{Dom}) \models \neg r_{prog}(X_1, \ldots, X_s, Y)$

$\leftrightarrow (\exists Z \cdot r_{prog}(X_1, \ldots, X_s, Y) \lor (r_{prog}(X_1, \ldots, X_s, Z) \land Y \neq Z))$

and hence, by using (1),

$M(\mathit{OpSem} \cup \mathit{Aux} \cup \mathit{Dom}) \models \neg \exists (\mathit{dom}_r(X_1, \ldots, X_s) \land \neg r_{prog}(X_1, \ldots, X_s, Y) \land \tilde{B})$

Thus, we have that
that is, clause \( \mathcal{S} \) is true in \( M(\text{OpSem} \cup \text{Aux} \cup \text{Dom}) \). We can conclude that \( M(\text{OpSem} \cup \text{Aux} \cup \text{Dom}) \) is a model of \( \text{Spec} \cup \text{Dom} \), and since \( M(\text{Spec} \cup \text{Dom}) \) is the least model of \( \text{Spec} \cup \text{Dom} \), we have that

\[
M(\text{Spec} \cup \text{Dom}) \subseteq M(\text{OpSem} \cup \text{Aux} \cup \text{Dom})
\]

Next we show that, for all integers \( p_1, \ldots, p_s, y \),

\[
M(\text{Spec} \cup \text{Dom}) \models \psi(p_1, \ldots, p_s, y) \text{ iff } M(\text{OpSem}) \models r_{\text{prog}}(p_1, \ldots, p_s, y)
\]

Only If Part of (4). Suppose that \( M(\text{Spec} \cup \text{Dom}) \models \psi(p_1, \ldots, p_s, y) \).

Then, by construction,

\[
M(\text{Spec} \cup \text{Dom}) \models r_{\text{prog}}(p_1, \ldots, p_s, y)
\]

and hence, by (3),

\[
M(\text{OpSem} \cup \text{Aux} \cup \text{Dom}) \models r_{\text{prog}}(p_1, \ldots, p_s, y)
\]

Since \( r_{\text{prog}} \) does not depend on predicates in \( \text{Aux} \cup \text{Dom} \),

\[
M(\text{OpSem}) \models r_{\text{prog}}(p_1, \ldots, p_s, y)
\]

If Part of (4). Suppose that \( M(\text{OpSem}) \models r_{\text{prog}}(p_1, \ldots, p_s, y) \).

Then, by definition of \( r_{\text{prog}} \),

\[
M(\text{Dom}) \models \text{dom}_x(p_1, \ldots, p_s)
\]

and

\[
M(\text{Spec}) \models \text{pre}(p_1, \ldots, p_s)
\]

Thus, by (6) and Condition (3.1) of Definition 1, there exists \( z \) such that

\[
M(\text{Spec}) \models \psi(p_1, \ldots, p_s, z)
\]

By (5) and (7),

\[
M(\text{Spec} \cup \text{Dom}) \models \psi(p_1, \ldots, p_s, z)
\]

By the Only If Part of (4),

\[
M(\text{OpSem}) \models r_{\text{prog}}(p_1, \ldots, p_s, z)
\]

and by the functionality of \( r_{\text{prog}} \), \( z = y \). Hence, by (8),

\[
M(\text{Spec} \cup \text{Dom}) \models \psi(p_1, \ldots, p_s, y)
\]

Let us now prove partial correctness. If \( M(\text{Spec}) \models \text{pre}(p_1, \ldots, p_s) \) and \( \text{prog} \) terminates, that is, \( M(\text{Dom}) \models \text{dom}_x(p_1, \ldots, p_s) \), then for some integer \( y \), \( M(\text{OpSem}) \models r_{\text{prog}}(p_1, \ldots, p_s, y) \). Thus, by (4), \( M(\text{Spec} \cup \text{Dom}) \models \psi(p_1, \ldots, p_s, y) \) and hence, by (2), \( M(\text{Spec}) \models \psi(p_1, \ldots, p_s, y) \). Suppose that the postcondition \( \psi \) is \( f(p_1, \ldots, p_s, z_k) \).

Then, by Condition (3.2) of Definition 1, \( y = z_k \).

Thus, \( \{\varphi\} \text{ prog } \{\psi\} \).

Removal of the Interpreter

Here we report the variant of the transformation presented in (De Angelis et al. 2014a) that we use in this paper to perform the removal of the interpreter. In this transformation we use the function \( \text{Unf}(C, A, \text{Cls}) \) defined as the set of clauses derived by unfolding a clause \( C \) with respect to an atom \( A \) using the set \( \text{Cls} \) of clauses (see the unfolding rule in Section 4.2).
The predicate \( \text{reach} \) is defined as follows:

\[
\text{reach}(X, X) \leftarrow \\
\text{reach}(X, Z) \leftarrow \text{tr}(X, Y), \text{reach}(Y, Z)
\]

where, as mentioned in Section 2, \( \text{tr} \) is a (nonrecursive) predicate representing one transition step according to the operational semantics of the imperative language.

In order to perform the Unfolding step, we assume that the atoms occurring in bodies of clauses are annotated as either unfoldable or not unfoldable. This annotation ensures that any sequence of clauses constructed by unfolding w.r.t. unfoldable atoms is finite. In particular, the atoms with predicate \( \text{initCf}, \text{finalCf} \), and \( \text{tr} \) are unfoldable. The atoms of the form \( \text{reach}(c_1, c_2) \) are unfoldable if \( c_1 \) is not associated with a while or goto command. Other annotations based on a different analysis of program \( \text{OpSem} \) can be used.

**Input:** Program \( \text{OpSem} \).

**Output:** Program \( \text{OpSem}_RI \) such that, for all integers \( p_1, \ldots, p_s, z_k \),

\[
\text{r}_\text{prog}(p_1, \ldots, p_s, z_k) \in M(\text{OpSem}) \text{ iff } \text{r}_\text{prog}(p_1, \ldots, p_s, z_k) \in M(\text{OpSem}_RI).
\]

**Initialization:**

\[
\text{OpSem}_RI := \emptyset; \quad \text{Defs} := \emptyset;
\text{InCls} := \{ \text{r}_\text{prog}(P_1, \ldots, P_s, Z_k) \leftarrow \text{initCf}(C_0, P_1, \ldots, P_s), \text{reach}(C_0, C_h), \text{finalCf}(C_h, Z_k) \};
\text{while} \text{ in } \text{InCls} \text{ there is a clause } C \text{ which is not a constrained fact do}
\text{Unfolding:}
\text{SpC} := \text{Unf}(C, A, \text{OpSem}), \text{ where } A \text{ is the leftmost atom in the body of } C;
\text{while} \text{ in } \text{SpC} \text{ there is a clause } D \text{ whose body contains an occurrence of an unfoldable atom } A \text{ do}
\text{SpC} := (\text{SpC} - \{D\}) \cup \text{Unf}(D, A, \text{OpSem})
etdowhile;
\text{Definition & Folding:}
\text{while} \text{ in } \text{SpC} \text{ there is a clause } E \text{ of the form: } H \leftarrow e, \text{reach}(c_1, c_2)
do
\text{if} \text{ in } \text{Defs} \text{ there is no clause of the form: } \text{newp}(V) \leftarrow \text{reach}(c_1, c_2)
\text{ where } V \text{ is the set of variables occurring in } \text{reach}(c_1, c_2)
\text{then} \text{ add the clause } N: \text{newp}(V) \leftarrow \text{reach}(c_1, c_2) \text{ to } \text{Defs} \text{ and } \text{InCls};
\text{SpC} := (\text{SpC} - \{E\}) \cup \{H \leftarrow e, \text{newp}(V)\}
etdowhile;
\text{InCls} := \text{InCls} - \{C\}; \quad \text{OpSem}_RI := \text{OpSem}_RI \cup \text{SpC};
etdowhile;
\]

RI: Removal of the Interpreter.

Let us now prove Theorem 3 stating the relevant properties of the RI transformation.

*The RI transformation terminates.* The termination of the Unfolding step is guaranteed by the unfoldable annotations. Indeed, (i) the repeated unfolding of the unfoldable atoms with predicates \( \text{initCf}, \text{finalCf}, \) and \( \text{tr} \), always terminates because
those atoms have no recursive clauses, (ii) by the definition of the semantics of the imperative program, the repeated unfolding of an atom of the form \( \text{reach}(c_{f_1}, c_{f_2}) \) eventually derives a new \( \text{reach}(c_{f_3}, c_{f_4}) \) atom where \( c_{f_3} \) is either a final configuration or a configuration associated with a while or goto command, and in both cases unfolding terminates. The termination of the Definition & Folding step follows from the fact that \( \mathcal{SP} \mathcal{C} \) is a finite set of clauses.

The outer while loop terminates because a finite set of new predicate definitions of the form \( \text{newp}(V) \leftarrow \text{reach}(c_{f_1}, c_{f_2}) \) can be introduced. Indeed, each configuration \( cf \) is represented as a term \( cf(LC,E) \), where \( LC \) is a labeled command and \( E \) is an environment (see Example 1). An environment is represented as a list of \((v,X)\) pairs where \( v \) is a variable identifier and \( X \) is its value, that is, a logical variable whose value may be subject to a given constraint. Considering that: (i) the labeled commands and the variable identifiers occurring in an imperative program are finitely many, and (ii) predicate definitions of the form \( \text{newp}(V) \leftarrow \text{reach}(c_{f_1}, c_{f_2}) \) abstract away from the constraints that hold on the logical variables occurring in \( c_{f_1} \) and \( c_{f_2} \), we can conclude that there are only finitely many such clauses (modulo variable renaming).

**Point 1:** \( \text{OpSem}_{RI} \) is a set of linear clauses over the integers. By construction, every clause in \( \text{OpSem}_{RI} \) is of the form \( H \leftarrow c, B \), where (i) \( H \) is either \( r_{\text{prog}}(p_1, \ldots, p_s, z_k) \) or \( \text{newp}(V) \), for some new predicate \( \text{newp} \) and tuple of variables \( V \), and (ii) \( B \) is either absent or of the form \( \text{newp}(V) \), for some new predicate \( \text{newp} \) and tuple of variables \( V \). Thus, every clause is a linear clause over the integers.

**Point 2:** \( \text{OpSem} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is satisfiable iff \( \text{OpSem}_{RI} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is satisfiable. From the correctness of the unfolding, definition, and folding rules with respect to the least model semantics of CLP programs (Etalle and Gabbrielli 1996), it follows that, for all integers \( p_1, \ldots, p_s, z_k \),

\[
   \text{r}_{\text{prog}}(p_1, \ldots, p_s, z_k) \in M(\text{OpSem}) \iff \text{r}_{\text{prog}}(p_1, \ldots, p_s, z_k) \in M(\text{OpSem}_{RI})
\]

\( \text{OpSem} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is satisfiable iff for every ground instance \( G \) of a goal in \( \text{F}_{\text{pcorr}} \),

\( M(\text{OpSem} \cup \text{Aux}) \models G \) since the only predicate of \( \text{OpSem} \) on which \( G \) may depend is \( \text{r}_{\text{prog}} \), by (1), we have that \( M(\text{OpSem} \cup \text{Aux}) \models G \) iff \( M(\text{OpSem}_{RI} \cup \text{Aux}) \models G \).

Finally, \( M(\text{OpSem}_{RI} \cup \text{Aux}) \models G \) for every ground instance \( G \) of a goal in \( \text{F}_{\text{pcorr}} \), iff \( \text{OpSem}_{RI} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is satisfiable.

**Point 3:** \( \text{OpSem} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is LA-solvable iff \( \text{OpSem}_{RI} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is LA-solvable.

Suppose that \( \text{OpSem} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \) is LA-solvable, and let \( \Sigma \) be an LA-solution of \( \text{OpSem} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \). Now we construct an LA-solution \( \Sigma_{RI} \) of \( \text{OpSem}_{RI} \cup \text{Aux} \cup \text{F}_{\text{pcorr}} \). To this purpose it is enough to define a symbolic interpretation for the new predicates introduced by \( \text{RI} \).

For any predicate \( \text{newp} \) introduced by \( \text{RI} \) via a clause of the form:

\[ \text{newp}(V) \leftarrow \text{reach}(c_{f_1}, c_{f_2}) \]

we define a symbolic interpretation as follows:

\[ \Sigma_{RI}(\text{newp}(V)) = \Sigma(\text{reach}(c_{f_1}, c_{f_2})) \]

Moreover, \( \Sigma_{RI} \) is identical to \( \Sigma \) for the atoms with predicate occurring in \( \text{OpSem} \).
Now we have to prove that $\Sigma_{RI}$ is indeed an LA-solution of $\text{OpSem}_{RI} \cup \text{Aux} \cup F_{pcorr}$. This proof is similar to the proof of Theorem 5 (actually, simpler, because $RI$ introduces new predicates defined by single atoms, while LIN introduces new predicates defined by conjunctions of atoms), and is omitted.

Vice versa, if $\Sigma_{RI}$ is an LA-solution of $\text{OpSem}_{RI} \cup \text{Aux} \cup F_{pcorr}$, we construct an LA-solution $\Sigma$ of $\text{OpSem} \cup \text{Aux} \cup F_{pcorr}$ by defining

$$\Sigma(\text{reach}(c_{f_1}, c_{f_2})) = \Sigma_{RI}(\text{newp}(V)).$$

Proof of Theorem 4

Let $\text{LCls}$ be a set of linear clauses and $\text{Gls}$ be a set of nonlinear goals. We split the proof of Theorem 4 in three parts:

Termination: The linearization transformation LIN terminates for the input set of clauses $\text{LCls} \cup \text{Gls}$;

Linearity: The output $\text{TransfCls}$ of LIN is a set of linear clauses;

Equisatisfiability: $\text{LCls} \cup \text{Gls}$ is satisfiable iff $\text{TransfCls}$ is satisfiable.

(Termination) Each UNFOLDING and DEFINITION & FOLDING step terminates. Thus, in order to prove the termination of LIN it is enough to show that the while loop is executed a finite number of times, that is, a finite number of clauses are added to $\text{NLCls}$. We will establish this finiteness property by showing that there exists an integer $M$ such that every clause added to $\text{NLCls}$ is of the form:

$$\text{newp}(X_1, \ldots, X_t) \leftarrow A_1, \ldots, A_k \quad (\dagger)$$

where: (i) $k \leq M$, (ii) for $i = 1, \ldots, k$, $A_i$ is of the form $p(X_1, \ldots, X_m)$, and (iii) $\{X_1, \ldots, X_t\} \subseteq \text{vars}(A_1, \ldots, A_k)$.

Indeed, let $M$ be the maximal number of atoms occurring in the body of a goal in $\text{Gls}$, to which $\text{NLCls}$ is initialized. Now let us consider a clause $C$ in $\text{NLCls}$ and assume that in the body of $C$ there are at most $M$ atoms. The clauses in the set $\text{LCls}$ used for unfolding $C$ are linear, and hence in the body of each clause belonging to the set $U(C)$ obtained after the UNFOLDING step, there are at most $M$ atoms. Thus, each clause in $U(C)$ is of the form $H \leftarrow c, A_1, \ldots, A_k$, with $k \leq M$. Since the body of every new clause introduced by the subsequent DEFINITION & FOLDING step is obtained by dropping the constraint from the body of a clause in $U(C)$, we have that every clause added to $\text{NLCls}$ is of the form $(\dagger)$, with $k \leq M$. Thus, LIN terminates.

(Linearity) $\text{TransfCls}$ is initialized to the set $\text{LCls}$ of linear clauses. Moreover, each clause added to $\text{TransfCls}$ is of the form $H \leftarrow c, \text{newp}(X_1, \ldots, X_t)$, and hence is linear.

(Equisatisfiability) In order to prove that LIN ensures equisatisfiability, let us adapt to our context the basic notions about the unfold/fold transformation rules for CLP programs presented in (Etalle and Gabbrielli 1996).

Besides the unfolding rule of Section 4.2, we also introduce the following definition and folding rules.

Definition Rule. By definition we introduce a clause of the form $\text{newp}(X) \leftarrow G$, where $\text{newp}$ is a new predicate symbol and $X$ is a tuple of variables occurring in $G$.

Folding Rule. Given a clause $E: H \leftarrow c, G$ and a clause $D: \text{newp}(X) \leftarrow G$ intro-
duced by the definition rule. Suppose that, \( X = \text{vars}(G) \cap \text{vars}(H,c) \). Then by folding \( E \) using \( D \) we derive \( H \leftarrow c, \text{newp}(X) \).

From a set \( \text{Cls} \) of clauses we can derive a new set \( \text{TransfCls} \) of clauses either by adding a new clause to \( \text{Cls} \) using the definition rule or by: (i) selecting a clause \( C \) in \( \text{Cls} \), (ii) deriving a new set \( \text{TransfC} \) of clauses using one or more transformation rules among unfolding and folding, and (iii) replacing \( C \) by \( \text{TransfC} \) in \( \text{Cls} \). We can apply a new sequence of transformation rules starting from \( \text{TransfCls} \) and iterate this process at will.

The following theorem is an immediate consequence of the correctness results for the unfold/fold transformation rules of CLP programs (Etalle and Gabbrielli 1996).

**Theorem 6 (Correctness of the Transformation Rules)**

Let the set \( \text{TransfCls} \) be derived from \( \text{Cls} \) by a sequence of applications of the unfolding, definition and folding transformation rules. Suppose that every clause introduced by the definition rule is unfolded at least once in this sequence. Then, \( \text{Cls} \) is satisfiable iff \( \text{TransfCls} \) is satisfiable.

Now, equisatisfiability easily follows from Theorem 6. Indeed, the UNFOLDING and DEFINITION & FOLDING steps of LIN are applications of the unfolding, definition, and folding rules (strictly speaking, the rewriting performed after unfolding is not included among the transformation rules, but obviously preserves all \( \text{LA} \)-models). Moreover, every clause introduced during the DEFINITION & FOLDING step is added to \( \text{NCls} \) and unfolded in a subsequent step of the transformation. Thus, the hypotheses of Theorem 6 are fulfilled, and hence we have that \( \text{LCls} \cup \text{Gls} \) is satisfiable iff \( \text{TransfCls} \) is satisfiable.

**Linearized clauses for Fibonacci.**

The set of linear constrained Horn clauses obtained after applying LIN is made out of clauses \( E_1, E_2, E_3, \) and \( C_3 \), together with the following clauses:

\[
\begin{align*}
\text{new1}(N1,U,V,U,N2,U,N3,U) & : - N1=0, N2<0, N3<0. \\
\text{new1}(N1,U,V,N2,U,N3,F3) & : - N1=0, N2<0, N4=N3-1, W=U+V, N3>=1, \text{new2}(N4,W,U,F3). \\
\text{new1}(N1,U,V,N2,F2,N3,U) & : - N1=0, N4=N2-1, W=U+V, N2>=1, N3<0, \text{new2}(N4,W,U,F2). \\
\text{new1}(N1,U,V,N2,F2,N3,F3) & : - N1=0, N4=N2-1, N2>=1, N3=N3-1, N3>=1, \text{new3}(N4,W,U,F2,N5,F3). \\
\text{new1}(N1,U,V,F1,N2,U,N3,U) & : - N4=N1-1, W=U+V, N1>=1, N2<0, N3<0, \text{new2}(N4,W,U,F1). \\
\text{new1}(N1,U,V,F1,N2,U,N3,F3) & : - N4=N1-1, N1>=1, N2<0, N5=N3-1, W=U+V, N3>=1, \text{new3}(N4,W,U,F1,N5,F3). \\
\text{new1}(N1,U,V,F1,N2,F2,N3,U) & : - N4=N1-1, N1>=1, N5=N2-1, W=U+V, N2>=1, N3<0, \text{new3}(N4,W,U,F1,N5,F2). \\
\text{new1}(N1,U,V,F1,N2,F2,N3,F3) & : - N4=N1-1, N1>=1, N5=N2-1, N2>=1, N6=N3-1, W=U+V, N3>=1, \text{new1}(N4,W,U,F1,N5,F2,N6,F3). \\
\text{new2}(N,U,V,U) & : - N<0. \\
\text{new2}(N,U,V,F) & : - N2=0, W=U+V, N>=1, \text{new2}(N2,W,U,F). \\
\text{new3}(N1,U,V,N2,U,N2) & : - N1=0, N2<0. \\
\text{new3}(N1,U,V,N2,F2) & : - N1=0, N3=N2-1, W=U+V, N2>=1, \text{new2}(N3,W,U,F2). \\
\text{new3}(N1,U,V,F1,N2,F2) & : - N3=N1-1, N1>=1, N4=N2-1, W=U+V, N2>=1, \text{new3}(N3,W,U,F1,N4,F2). \\
\text{new3}(N1,U,V,F1,N2,U) & : - N3=N1-1, W=U+V, N1>=1, N2<0, \text{new2}(N3,W,U,F1).
\end{align*}
\]
Proof of Theorem 5 (Monotonicity with respect to LA-Solvability).

Suppose that the set $LCls \cup Gls$ of constrained Horn clauses is LA-solvable, and let $TransfCls$ be obtained by applying LIN to $LCls \cup Gls$. Let $\Sigma$ be an LA-solution of $LCls \cup Gls$. We now construct an LA-solution of $TransfCls$. For any predicate $newp$ introduced by LIN via a clause of the form:

$\text{new}(X_1, \ldots, X_i) \leftarrow A_1, \ldots, A_k$

we define a symbolic interpretation $\Sigma'$ as follows:

$\Sigma'(\text{new}(X_1, \ldots, X_i)) = \Sigma(A_1) \land \ldots \land \Sigma(A_k)$

Now, we are left with the task of proving that $\Sigma'$ is indeed an LA-solution of $TransfCls$. The clauses in $TransfCls$ are either of the form

$\text{false} \leftarrow c, \text{new}(X_1, \ldots, X_u)$

or of the form

$\text{new}(X_1, \ldots, X_i) \leftarrow c, \text{new}(X_1, \ldots, X_u)$

where $\text{new}$ and $\text{newq}$ are predicates introduced by LIN. We will only consider the more difficult case where the conclusion is not $\text{false}$.

The clause $\text{new}(X_1, \ldots, X_i) \leftarrow c, \text{new}(X_1, \ldots, X_u)$ has been derived (see the linearization transformation LIN in Figure 2) in the following two steps.

(Step i) Unfolding $\text{new}(X_1, \ldots, X_i) \leftarrow A_1, \ldots, A_k$ w.r.t. all atoms in its body using $k$ clauses in $LCls$:

$A_1 \leftarrow c_1, B_1 \ldots \quad A_k \leftarrow c_k, B_k$

where some of the $B_i$’s can be the true and $c \equiv c_1, \ldots, c_k$, thereby deriving

$\text{new}(X_1, \ldots, X_i) \leftarrow c_1, \ldots, c_k, B_1, \ldots, B_k$

(Without loss of generality we assume that the atoms in the body of the clauses are equal to, instead of unifiable with, the heads of the clauses in $LCls$.)

(Step ii) Folding $\text{new}(X_1, \ldots, X_i) \leftarrow c_1, \ldots, c_k, B_1, \ldots, B_k$ using a clause of the form:

$\text{new}(X_1, \ldots, X_u) \leftarrow B_1, \ldots, B_k$

Thus, for $\text{new}(X_1, \ldots, X_u)$ we have the following symbolic interpretation:

$\Sigma'(\text{new}(X_1, \ldots, X_u)) = \Sigma(B_1) \land \ldots \land \Sigma(B_k)$

To prove that $\Sigma'$ is an LA-solution of $TransfCls$, we have to show that

$LA \models \forall (c \land \Sigma'(\text{new}(X_1, \ldots, X_u))) \rightarrow \Sigma'(\text{new}(X_1, \ldots, X_i))$

Assume that

$LA \models c \land \Sigma'(\text{new}(X_1, \ldots, X_u))$

Then, by definition of $\Sigma'$,

$LA \models c \land \Sigma(B_1) \land \ldots \land \Sigma(B_k)$

Since $\Sigma$ is an LA-solution of $LCls$, we have that:

$LA \models \forall (c_1 \land \Sigma(B_1)) \rightarrow \Sigma(A_1)) \ldots \quad LA \models \forall (c_k \land \Sigma(B_k) \rightarrow \Sigma(A_k))$

and hence

$LA \models \Sigma(A_1) \land \ldots \land \Sigma(A_k)$

Thus, by definition of $\Sigma'$,

$LA \models \Sigma'(\text{new}(X_1, \ldots, X_i))$.

$\square$
