Table 1: Test beds used in the literature of the BRP

1 Description of the data set

In this document we report the computational results obtained by means of the Bounded Beam Search (BBS) algorithm. For all the tests we use a machine with a CPU Intel Core i7-3632QM at 2.2GHz and with 1 GB RAM under a Linux operating system. We set one second as time limit for the solution of each instance.

We considered several sets of instances presented in the literature, divided into six groups that are resumed in Table 1. In the following, w is the number of stacks, h the height of each stack and n the number of blocks in a yard.

GROUP 1 is defined by the instances presented in Wan et al. (2009), all with six stacks of height between two and five. The storage densities of the stacks are classified as light (L), medium (M), and heavy (H), according to the percentage of operating capacity taken up. In particular, an instance with w stacks of height h is light if then number n of blocks is $0.2 \times ((w - 1) \times h + 1)$, is medium if $n = 0.5 \times ((w - 1) \times h + 1)$, and heavy if $n = 0.8 \times ((w - 1) \times h + 1)$. In total, 12 combinations of stack sizes and storage densities are considered, each composed by 50 instances.

The instances of GROUP 2 (Wu and Ting (2010)) are grouped according to the number of stacks $3 \leq w \leq 12$ and height $3 \leq h \leq 12$. Therefore, we have 100 problem classes, each with 40 instances. For each instance, the number of blocks $n = w \times h - (h - 1)$.

The instances of GROUP 3 (Lee and Lee (2010)) are defined on multiple bays yards. Here, we consider only the subset of the 70 *Individual* ones, i.d. those where the block have distinct priorities. The instances can be *Random* (R), when the blocks are randomly located in the available slots, or *Upside down* (U), when blocks with higher retrieval priority are located in the lower slots of the stacks. All of them have up to 10 bays, $3 \leq w \leq 16$ and $h \in \{6, 8\}$, and $70 \leq n \leq 720$. Here we allow reshuffle of blocks between different bays: therefore, an instance with 10 bays and 16 stacks is equivalent to an instance with 1 bay and 160 stacks.

GROUP 4 includes a set of 880 instances introduced in Caserta et al. (2011). Such instances are randomly generated with $w \in \{3, 4, 5, 6, 10, 100\}$, $h \in \{5, 6, \dots, 12, 102\}$ and $n = w \times (h - 2)$.

The 8000 instances of GROUP 5 (Unluyurt and Aydin (2012)) are generated with $w \in [3, 7]$, $h = [4, 7]$ and different densities of the blocks. They can be *balanced*

(b), if the stacks have the same number of stored blocks, or *unbalanced* (u).

In GROUP 6, we consider the 12500 instances described in Zhu et al. (2012). Such instances are grouped into 125 classes of size 100, according to the values of $w \in [6, 10]$, $h \in [3, 7]$, and $n \in [(w - 1) \times h, w \times h - 1]$.

We also introduce a new set of instances, LBRI. The procedure implemented to generate the new instances follows the scheme introduced in Zhu et al. (2012). Here the authors show that it is always possible to retrieve all the blocks of a yard with w stacks of height h and n blocks if any block i is located in a slot $t_i \leq h$ such that $h - t_i \leq w \cdot h - n + (i - 1)$. Then, for any triple (w, h, n) , with $n \leq w \times h$, the instance generation procedure is the following: we first randomly order the n blocks and then, according to this order, we iteratively assign each block to the first available slot of an available randomly selected stack. If the yard generated this way does not fit the feasibility condition defined above, then it is discarded and regenerated. The set LBRI consists of 8400 instances, 100 for each triple $w \in \{50, 100, 500, 1000\}$, $h \in \{4, 7, 10\}$ and $n \in [w \cdot (h - 1), w \cdot h - 1]$.

For each set of instances, we report a table with detailed results. In the tables, Name denotes the name of the instance, w indicates the number of stacks, h the number of available slots for each stack, n the number of blocks, and #I is the number of instances of the group. Resh and Time denote the number of reshuffles and the computing time obtained by means of our BBS algorithm, respectively.
